

s.

# Architectural design

- An early stage of the system design process.
- Represents the link between specification and design processes.
- Often carried out in parallel with some specification activities.
- It involves identifying major system components and their communications.

, 8th e

n. Chapter 11

# Advantages of explicit architecture Stakeholder communication Architecture may be used as a focus of discussion by system stakeholders. System analysis Means that analysis of whether the system can meet its non-functional requirements is possible.

- Large-scale reuse
  - The architecture may be reusable across a range of systems.

on. Chapter 11

Slide

## Architecture and system characteristic

## Performance

Localise critical operations and minimise communications. Use large rather than fine-grain components.

- Security
- Use a layered architecture with critical assets in the inner ٠ layers
- Safety

©Ian Sommerville 2006

- Localise safety-critical features in a small number of subsystems
- Availability
- Include redundant components and mechanisms for fault tolerance.

Sth edit

- Maintainability
- Use fine-grain, replaceable components.

## Architectural conflicts

Slide 12

n. Chapter 11

8th edition. Chapter 11

Chapter 11

- Using large-grain components improves performance but reduces maintainability.
- Introducing redundant data improves availability but makes security more difficult.
- Localising safety-related features usually means more communication so degraded performance.

# Packing robot control system Vision system Object identificat Arm controller Gripper controller Conveyor controller

# System structuring

- Concerned with decomposing the system into interacting sub-systems.
- The architectural design is normally expressed as a block diagram presenting an overview of the system structure.
- · More specific models showing how subsystems share data, are distributed and interface with each other may also be developed.

# Box and line diagrams

ı. Cha oter 11 Å

ering, 8th edition. Chapter 11

- Very abstract they do not show the nature of component relationships nor the externally visible properties of the sub-systems.
- However, useful for communication with stakeholders and for project planning.

# Architectural design decisions

- Architectural design is a creative process so the process differs depending on the type of system being developed.
- However, a number of common decisions span all design processes.

## Architectural design decisions

- Is there a generic application architecture that can be used?
- How will the system be distributed?
- What architectural styles are appropriate?
- What approach will be used to structure the system?
- How will the system be decomposed into modules?
- What control strategy should be used?
- How will the architectural design be evaluated?
- How should the architecture be documented?

# Architecture reuse

- Systems in the same domain often have similar architectures that reflect domain concepts.
- Application product lines are built around a core architecture with variants that satisfy particular customer requirements.
- Application architectures are covered in Chapter 13 and product lines in Chapter 18.

15

# System organisation

- Reflects the basic strategy that is used to structure a system.
- Three organisational styles are widely used:

n. Chapter 11

- A shared data repository style;
- A shared services and servers style;
- An abstract machine or layered style.

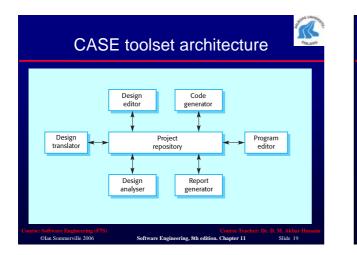

# The repository model

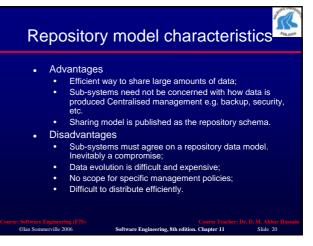

- Sub-systems must exchange data. This may be done in two ways:
  - Shared data is held in a central database or repository and may be accessed by all subsystems;
  - Each sub-system maintains its own database and passes data explicitly to other sub-systems.

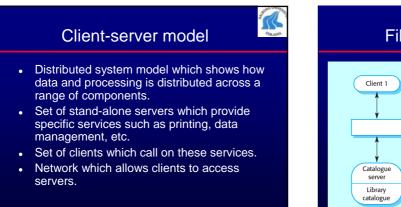

ng, 8th edition. Chapter 11

Slide 18

 When large amounts of data are to be shared, the repository model of sharing is most commonly used.

# **Client-server characteristics**

re Engir

#### Advantages

٠

©Ian So

wille 200

©Ian Sommerville 2006

- Distribution of data is straightforward;
- Makes effective use of networked systems. May require cheaper hardware;
- Easy to add new servers or upgrade existing servers. Disadvantages
- Disadvantages
- No shared data model so sub-systems use different data organisation. Data interchange may be inefficient;
- Redundant management in each server;

are Eng

 No central register of names and services - it may be hard to find out what servers and services are available.

ering, 8th edition. Chapter 11

# Abstract machine (layered) mode

- Used to model the interfacing of sub-systems.
- Organises the system into a set of layers (or abstract machines) each of which provide a set of services.
- Supports the incremental development of subsystems in different layers. When a layer interface changes, only the adjacent layer is affected.
- However, often artificial to structure systems in this way.

# Modular decomposition styles

- Styles of decomposing sub-systems into modules.
- No rigid distinction between system organisation and modular decomposition.

Slide 26

. Chapter 11

K

# **Object models**

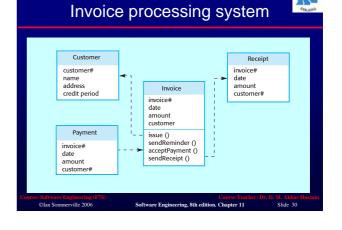

- Structure the system into a set of loosely coupled objects with well-defined interfaces.
- Object-oriented decomposition is concerned with identifying object classes, their attributes and operations.
- When implemented, objects are created from these classes and some control model used to coordinate object operations.

ing, 8th edi

e En

n. Chapter 11

©Ian S

## Object model advantages

- · Objects are loosely coupled so their implementation can be modified without affecting other objects.
- The objects may reflect real-world entities.
- OO implementation languages are widely used.
- However, object interface changes may • cause problems and complex entities may be hard to represent as objects.

ter 11

## Function-oriented pipelining

- Functional transformations process their inputs to produce outputs.
- May be referred to as a pipe and filter model (as in UNIX shell).
- Variants of this approach are very common. When transformations are sequential, this is a batch sequential model which is extensively used in data processing systems.

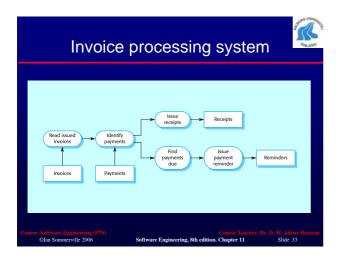

g, 8th edition, Chapter 11

Slide 32

Slide 34

Slide 36

Not really suitable for interactive systems.

# Pipeline model advantages

- Supports transformation reuse.
- Intuitive organisation for stakeholder communication.
- Easy to add new transformations.
- Relatively simple to implement as either a concurrent or sequential system.
- However, requires a common format for data • transfer along the pipeline and difficult to support event-based interaction.

re Engineering, 8th edition. Chapter 11

## st **Control styles** Are concerned with the control flow between sub-systems. Distinct from the system decomposition model. Centralised control One sub-system has overall responsibility for control and starts and stops other sub-systems. **Event-based control** Each sub-system can respond to externally generated events from other sub-systems or the system's environment. ion. Chapter 11 Slide 3 ring, 8th editi

# Centralised control

A control sub-system takes responsibility for managing the execution of other sub-systems.

#### Call-return model

©Ian Sommerville 200

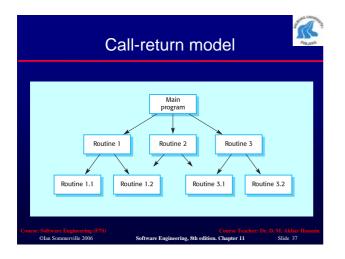

Top-down subroutine model where control starts at the top of a subroutine hierarchy and moves downwards. Applicable to sequential systems.

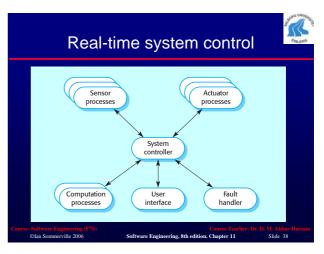

## Manager model

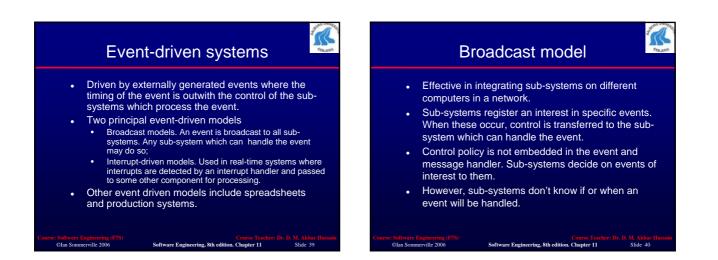

Applicable to concurrent systems. One system component controls the stopping, starting and coordination of other system processes. Can be implemented in sequential systems as a case statement.

ing, 8th edition. Chapter 11

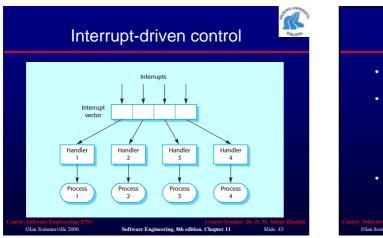

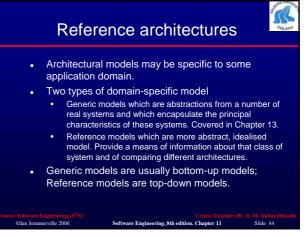

# **Reference architectures**

R

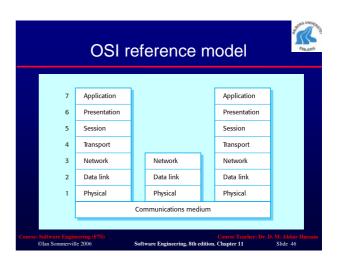

Slide 45

A

- Reference models are derived from a study of the application domain rather than from existing systems.
- May be used as a basis for system implementation or to compare different systems. It acts as a standard against which systems can be evaluated.
